

**Today's agenda:**

Computation with pure LC

Reductions in LC

**Computation with pure LC : example [ $\alpha$ -axiom,  $\beta$ -axiom]**Eg:  $S = (\lambda xyz. ((x z) (y z)))$        $I = (\lambda x.x)$       Compute  $SII$ 

For the sake of illustration, let us remove some parentheses s.t. the meaning remains same

 $S = \lambda xyz. (x z) (y z)$  $SII = (\lambda xyz. (x z) (y z)) (\lambda x.x) (\lambda x.x)$  $= ( (\lambda xyz. (x z) (y z)) (\lambda \textcolor{red}{x}.x) ) (\lambda x.x)$        $SII = (SI)I$       since  $fgh = (fg) h$ We want to have unique names: no repetition of names, so use  $\alpha$ -axiom $=_{\beta} ( (\lambda xyz. (x z) (y z)) (\lambda \textcolor{blue}{u}.u) ) (\lambda \textcolor{red}{x}.x)$       [portion in red above where  $x$  is replaced with  $u$ ]Now we rename the  $x$  on the rightmost side to get $=_{\beta} ( (\lambda xyz. (\textcolor{blue}{x} z) (y z)) (\lambda \textcolor{blue}{u}.u) ) (\lambda \textcolor{blue}{v}.v)$       form     $M N P$ use  $\beta$ -axiom: replacing  $\textcolor{red}{x}$  by  $\lambda u.u$  $=_{\beta} ((\lambda yz. ((\lambda \textcolor{blue}{u}.u) z) (y z)) (\lambda \textcolor{blue}{v}.v))$        $A$  $=_{\beta} ( (\lambda \textcolor{red}{y}z. (z (\textcolor{red}{y} z)) ) (\lambda \textcolor{blue}{v}.v)$        $B$ Now we have to apply, so  $\textcolor{red}{y}$  would be replaced by  $\lambda v.v$  $=_{\beta} \lambda z. (z ((\lambda \textcolor{blue}{v}.v) z))$        $F$  $=_{\beta} \lambda z. z z$        $E$  which is in normal form--cannot be reduced any further.**Normal form** means simplest form

A lambda expression that cannot be beta-reduced is in normal form.

Eg,  $(2+1) * (3+2) + (5+2)*2$  $= (3)*(5) + (7)*2$  $= 15+14$  $= 29$ —normal formAn abstraction is always in a normal form, if the body is in normal form. We need to apply beta rules when a term is of the form  $M N$ .

from previous lecture, term rewriting and beta reduction are same.

**Reductions** *Term rewriting is another way of doing computation.*

There are two types of reduction of lambda terms: CBN (call-by-name), CBV (call-by-value).

The terms would be of the form  $(M\ N)$

CBN: take  $N$  as it is and replace  $x$  in  $M$  as above.

simplify  $M$   
simplify  $N$   
beta reduction

CBV: simplify  $N$  as much as possible (normal form) and then the resultant term would be applied for  $M$ .

**Example:**

Eg1,  $(\lambda x. x + x) ((\lambda y. y) 5)$  of the form  $M\ (N\ P)$

CBN:  $= (\lambda y. y)5 + ((\lambda y. y)5) = 5+5 = 10$  replace  $x$  with  $(N\ P)$  as it is

CBV:  $= (\lambda x. x + x) 5 = 5+5 = 10$ . Simplify  $(N\ P)$  to say  $v$  and then replace  $x$  with  $v$

CBV semantics says that  $N$  would be reduced to a value before calling the function.

In CBN:  $N$  is evaluated only when needed. This is called lazy rewriting. (call by need)

Haskell uses Call by Need also called Lazy beta reduction or lazy rewriting

Haskell uses CBN, and lazy rewriting is an important feature in Haskell.

*CBN is guaranteed to reach a normal form, if one exists;*

CBV may get stuck, forever evaluating an argument that would never be used.

Eg2,  $(\lambda x. z + z) ((\lambda y. y) 5)$  there is no free occurrence of  $x$ ; so the answer would be  $z+z$ .

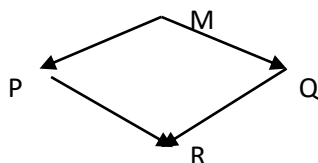

But CBV would evaluate  $(N\ P)$ —which as we can see is not required in this case.

What if  $(N\ P)$  is non-terminating? CBV would get stuck although there exists a normal form.

**Church-Rosser Theorem:** For all pure lambda terms  $M, P, Q$ , if  $M$  reduces to  $P$  ( $M \Rightarrow^* P$ ) and  $M$  reduces to  $Q$  ( $M \Rightarrow^* Q$ ) then there must exist a term  $R$  such that  $P \Rightarrow^* R$  and  $Q \Rightarrow^* R$ .  $M \Rightarrow^* P$  means zero or more alpha renaming and beta-reductions.

The theorem says that order of reduction does not influence the end result. The end result is in normal form, if one exists.

The above property is also called diamond property or confluence diagram.

For a lambda term, there is a unique normal form, but there are various ways to reach that normal form.

**Exercise:** (i) Give another way of computing SII. (ii) Give all possible ways of computing SII. (iii) Draw the confluence diagram.

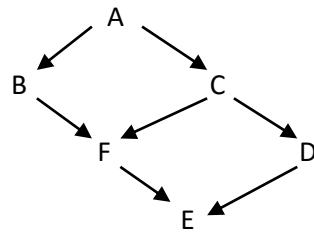

Another way of computing SII:

$$=_{\beta} ( (\lambda yz. ( (\lambda u.u) z) (\underline{y}z) ) (\lambda v.v) ) \quad A$$

$$=_{\beta} \lambda z. ( (\lambda u.u) z) (\underline{(\lambda v.v) z}) \quad C$$

$$=_{\beta} \lambda z. \underline{(\lambda u.u) z z} \quad D$$

$$=_{\beta} \lambda z. z z \quad E \quad \text{u is replaced by } z z$$
